

The run environment: the physics the market already prices

Temperature

warm air is thinner →
ball carries ~+2.5 ft per +10°F

Humidity

humid air is LESS dense →
slightly more carry (counter-intuitive)

Wind to center

out: more carry, more runs
in: knocks fly balls down

Park factor

100 = neutral · 112 = hitter
120+ ≈ Coors (altitude, thin air)

Fly-ball carry $\approx f(\text{air density})$: temperature, altitude,
barometric pressure, humidity, wind. Denser air = less carry = fewer runs.
